

## AIR BAG APPARATUS FOR A SCOOTER TYPE MOTORCYCLE

### BACKGROUND OF THE INVENTION

#### CROSS-REFERENCE TO RELATED APPLICATIONS

[001] The present nonprovisional application claims priority under 35 USC 119 to Japanese Patent Application No. 2002-060864 filed on March 6, 2002 and Japanese Patent Application No. 2002-029523 filed on February 6, 2003 the entire contents thereof is hereby incorporated by reference.

#### Field of the Invention

[002] The present invention relates to an air bag apparatus for a scooter type motorcycle, having an air bag that is capable of restraining an operator on a seat from a front direction, in response to expansion of the air bag.

#### Description of Background Art

[003] Conventionally, a type of air bag apparatus is known, for example, as disclosed in the Gazette of Japanese Patent Application Laid-Open No. Hei 9-328053.

[004] However, with the conventional apparatus, there is a possibility that the operator cannot be restrained sufficiently, even when the air bag expands in front of the operator on the seat, in the case where yaw behavior and/or rolling behavior of the vehicle body are/is large. In order to achieve a secured restraint, it is necessary to enlarge the expansion volume of the air bag, and accordingly, other components, such as an inflator, tend to become oversized.

## SUMMARY AND OBJECTS OF THE INVENTION

[005] It is an object of the present invention to provide an air bag apparatus for a scooter type motorcycle, which is capable of securely restraining the operator on the seat, without a need for enlarging the expansion volume of the air bag, even when the yaw behavior and/or rolling behavior of the vehicle body are/is large.

[006] In order to achieve the above objective, the present invention provides an air bag apparatus for a scooter type motorcycle that includes an air bag that is capable of restraining an operator on a seat from a front direction in response to an expansion of the air bag, wherein, the air bag and a vehicle body in the rear of the seat are linked via restraining belts or restraining nets, being a pair at right and left, which are stored in the vehicle body when the air bag is in a folded state, and which become in a state of tension on both exterior sides at the right and left of an operator on the seat, when the air bag expands.

[007] With the configuration of the invention, the restraining belts or the restraining nets are arranged in a state of tension on the both right and left exterior sides of the operator on the seat, at the time of the air bag expansion in response to the action of a shock against the vehicle. Therefore, it is possible to restrain the operator from the both right and left sides, with the restraining belts or the restraining nets, even when the yaw behavior and/or the rolling behavior of the vehicle body are/is large. Accordingly, it is possible to securely restrain the operator from a front direction, even with the air bag having a small expansion volume.

[008] The present invention includes a vehicle body cover constituting the vehicle body together with a vehicle body frame having a head pipe on a front end thereof. The head pipe supports a front fork in an orientation-manipulative manner and includes a front cover, which covers a circumference of the head pipe, and an air bag housing for storing the air bag installed at a forward position of the seat in the rear of the front cover. With this configuration, on a scooter type motorcycle having a concave shape between the seat and the head pipe, formed by denting downwardly the vehicle body, it is possible by the air bag, to securely restrain the operator on the seat from a front direction, without a large modification of the vehicle body shape.

[009] Furthermore, the vehicle body cover includes, in addition to the front cover, a pair of leg shields at the right and left for covering forward portions of the operator's legs. The leg shields are joined with both right and left sides of the front cover, respectively. A pair of footrest sections are provided at the right and left connecting, respectively, to the leg shields for supporting the feet of the operator. A rear cover is jointed with the footrest sections, for covering both right and left sides of a rear part of the vehicle body frame, wherein, the restraining belts or the restraining nets, an end of which is fixedly linked with the air bag and another end of which is linked with the rear cover, are stored in storage grooves, being a pair at right and left, which are provided over along the front cover, the leg shields, the footrest sections and the rear cover, in such a manner to allow the restraining belts or the restraining nets to be pulled out, in response to a tension thereof, with expansion of the air bag. With this configuration, it is possible for the scooter type motorcycle having footrest sections formed between the seat and the front cover, to store the restraining belts or the restraining nets, so as not to be obstacles at the time of getting on/off and driving, as well as maintaining a natural external view, when the air bag is in a state of non-expanded.

[0010] Further scope of applicability of the present invention will become apparent from the detailed description given hereinafter. However, it should be understood that the detailed description and specific examples, while indicating preferred embodiments of the invention, are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art from this detailed description.

#### BRIEF DESCRIPTION OF THE DRAWINGS

[0011] The present invention will become more fully understood from the detailed description given hereinbelow and the accompanying drawings which are given by way of illustration only, and thus are not limitative of the present invention, and wherein:

[0012] Fig. 1 is a side view of a scooter type motorcycle of the first embodiment of the present invention;

[0013] Fig. 2 is an enlarged cross sectional view of Fig. 1, taken along line 2-2;

[0014] Fig. 3 is a side view of the scooter type motorcycle, at the time of air bag expansion;

[0015] Fig. 4 is a plan view of Fig. 3; and

[0016] Fig. 5 is a side view of a scooter type motorcycle of the second embodiment of the present invention.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0017] Hereinafter, modes for carrying out the present invention will be explained, based on the embodiments of the present invention as shown in the attached drawings.

[0018] As illustrated in Fig. 1, a head pipe 6 is provided at a front end of a vehicle body frame 5 of a scooter type motorcycle. A front fork 7 is supported in orientation-manipulative manner with a front wheel WF axially supported at the lower end of the front fork 7. An orientation-manipulating handle 8 is coupled with the upper portion of the front fork 7.

[0019] At a midway point between the front and rear of the vehicle body frame 5, a power unit 9 containing an engine and a transmission is mounted. A rear wheel WR is axially supported at the rear on a swing arm 10 which is supported by the rear portion of the power unit 9, in such a manner that movement up and down is possible. Further, power from the power unit 9 is transmitted to the rear wheel WR via an endless type chain 17.

[0020] A rear shock absorber unit 13 is installed between a seat rail 12 and the swing arm 10, which are provided in the rear of the vehicle body frame 5.

[0021] The vehicle body frame 5 is covered with a vehicle body cover 15, made of synthetic resin, which constitutes the vehicle body 14 together with the vehicle body frame 5. The vehicle body cover 25 covers a circumference of the head pipe 6, and further includes a front cover 16 for covering the front wheel WF from above. A pair of leg shields 17 are provided at the right and left for covering a forward portion of

the operators legs. The leg shields are joined with both right and left sides of the front cover 16, respectively. A pair of footrest sections 18 are provided at the right and left that are connecting to the leg shields 17, respectively, so as to support the feet of the operator. A floor tunnel section 19 is raised upwardly between the footrest sections 18, skirt sections 20 that are hanging downwardly from outer edges of the both footrest sections 18, respectively, and a rear cover 21 which is joined with the footrest sections 18 and the floor tunnel section 19, covering the both right and left sides of the rear part of the vehicle body frame 5.

[0022] On the rear cover 21 is mounted a front seat 22 on which an operator sits, and a rear seat 23, on which a passenger sits with the rear seat being arranged in the rear of the front seat 22.

[0023] Fig. 2 illustrates an air bag module 24 of the air bag apparatus that is installed at a position in front of the operator sitting on the front seat 22, for example, to the rear of the front cover 16,.

[0024] The air bag module 24 comprises an air bag housing 25, an air bag 26 stored in the air bag housing 25, and an inflator 27 to generate gas for expanding the air bag 26.

[0025] The air bag housing 25 comprises a storage tube unit 28, which is formed in the shape of tube having a tangible bottom, made of synthetic resin, in such a manner that it is capable of storing the air bag 26 in a folded manner. A cover unit 29 is provided for closing an upper end opening of the storage tube unit 28. The storage tube unit 28 is installed in the rear of the front cover 16, either integrally or as a separate member.

[0026] On the periphery of the cover unit 29, a fragile portion 29a is provided, except for one point in the peripheral direction. The fragile portion 29a is formed in such a manner that it is capable of easily bursting.

[0027] The air bag 26 is formed in a shape of bag, having an opening portion 26a on the undersurface thereof, and it is stored in the air bag housing 25, in a folded manner. Further, the inflator 27 is supported by a cap 30 that is mounted fixedly to the

opening portion 26a on the undersurface of the air bag 26. The cap 30 is fixed on a block end of the storage tube unit 28.

[0028] A shock detecting sensor (not shown), such as an acceleration sensor, is installed on the vehicle body frame 5. The inflator 27 is activated in response to the detection of a shock not smaller than a predetermined value by the shock detecting sensor so as to provide a high pressure gas into the air bag 26.

[0029] At a position corresponding to the fragile portion 29a and between the storage tube unit 28 and the cover unit 29 of the air bag housing 25, a pair of through holes 32, 32 are provided at right and left portions thereof. Ends of restraining belts 31, 31 are provided as a pair at right and left portions that are made of nylon, for example, and are inserted through both of the through holes 32, 32, respectively, into the air bag housing 25, so that the restraining belts are fixedly joined with both sides of the air bag 26, respectively.

[0030] The other ends of both restraining belts 31, 31 are fixedly attached to both right and left sides of the rear cover 21 of the vehicle body 14, to the rear of the front seat 22. The length of the restraining belts 31, 31 becomes short so that the belts can be stored in the vehicle body 14 when the air bag 26 is folded within the air bag housing 25. On the other hand, when the air bag 26 expands, the restraining belts are set to be in a state of tension on both the right and left exterior sides of the operator positioned on the front seat 22.

[0031] On the vehicle body cover 15 of the vehicle body 14, a pair of storage grooves 34 are provided at the right and left allowing the restraining belts 31, 31 to be stored therein. The storage grooves 34 are provided over along the front cover 16, the leg shield 17, the footrests 18 and the rear cover 21. These storage grooves 34 are covered with a cover (not shown), which is capable of bursting in accordance with the tension of the restraining belts 31, 31 accompanied with expansion of the air bag 26. In other words, the restraining belts 31 are stored in the storing grooves 34, so as to be pulled out in response to the tension of the restraining belts 31, with the expansion of the air bag 26.

[0032] Next, an operation of the first embodiment will be explained. When the shock detecting sensor detects a shock of not smaller than a predetermined value, due to a collision and the like, the inflator 27 is activated and provides high pressure gas into the air bag 26. Then, as shown in Fig. 3 and Fig. 4, the air bag 26 allows the fragile part 29a of the air bag housing 25 to burst, and expands upwardly instantaneously, along with the opening of the cover unit 29. Accordingly, the operator sitting on the front seat 22 is restrained from the front direction with the thus expanded air bag 26.

[0033] In the meantime, the air bag 26 and the rear cover 21 of the vehicle body 14 positioned to the rear of the front seat 22 are linked via restraining belts 31, 31, being a pair at right and left belts, which are stored in the vehicle body cover 15 of the vehicle body 14, when the air bag 26 is in a state of folded, and which come into a state of tension, at right and left exterior sides of the operator on the seat 22, when the air bag expands.

[0034] Accordingly, when the air bag 26 expands, the restraining belts 31, 31 are arranged in a state of tension at right and left exterior sides of the operator on the front seat 22, whereby the operator can be restrained from both the right and left sides with the restraining belts 31, 31, even if a yaw behavior and/or a rolling behavior of the vehicle body 14 are/is large. Therefore, it is possible to securely restrain the operator from the front direction, even with the air bag 26 has a small expansion volume.

[0035] In addition, since the air bag housing 25 for storing the air bag 26 is installed at a forward position of the front seat 22 and in the rear of the front cover 16, a scooter type motorcycle having a concave shape between the front seat 22 and the head pipe 6, formed by denting downwardly the vehicle body 14, does not need a large modification of the vehicle body shape. Thus, it is possible for the air bag 26 to securely restrain the operator on the front seat 22 from a front direction.

[0036] Moreover, the restraining belts 31, an end of which is fixedly linked with the air bag 26 and another end of which is linked with the rear cover 21 are stored in a pair of storage grooves 34 at the right and left, which are provided over along the front cover 16, the leg shields 17, the footrest sections 18 and the rear cover 21, in

such a manner so as to allow the restraining belts 31 to be pulled out, in response to a tension thereof, with expansion of the air bag 26. With this configuration, it is possible for the scooter type motorcycle having footrest sections 18 formed between the front seat 22 and the front cover 16 to store the restraining belts 31 so as not to be obstacles at the time of getting on/off the vehicle or when driving the vehicle, as well as maintaining a natural external view, when the air bag 26 is in a state of being non-expanded.

[0037] Fig. 5 shows the second embodiment of the present invention, and to the parts corresponding to first embodiment, explanations of the identical reference numbers are applied.

[0038] The air bag 26 for restraining the operator on the front seat 22 from the front direction in response to an expansion of the air bag, and the rear cover 21 of the vehicle body 14 in the rear of the front seat 22 are linked via a pair of restraining nets 35 positioned at the right and left, which are stored in the vehicle body cover 15 of the vehicle body, when the air bag 26 is in a state of folded, and which come into a state of tension in the both right and left exterior sides of the operator on the front seat 22, when the air bag 26 expands. These restraining nets 35 are made of nylon, for example.

[0039] Similar effects as achieved by the first embodiment can be attained by the second embodiment.

[0040] The embodiments of the present invention have been explained above, but the present invention is not limited to the embodiments thus described and various design changes are possible without deviating from the present invention as defined in the claims.

[0041] According to the present invention, restraining belts or restraining nets are arranged in a state of tension at right and left exterior sides of an operator on the seat, when the air bag expands. Therefore, it is possible to restrain the operator from both right and left sides with restraining belts or the restraining nets, even if a yaw behavior and/or a rolling behavior of the vehicle body are/is large, whereby the operator can be securely restrained even with the air bag having a small expansion volume.

[0042] Furthermore, according to the present invention, a scooter type motorcycle having a concave shape between the seat and the head pipe, formed by denting downwardly the vehicle body, does not need a large modification, of the vehicle body shape, and it is possible by the air bag, to securely restrain the operator on the seat from a front direction.

[0043] Furthermore, according to the present invention, it is possible for the scooter type motorcycle having footrest sections formed between the seat and the front cover to store the restraining belts or restraining nets, so as not to be obstacles at the time of getting on/off the vehicle or when driving the vehicle, as well as maintaining a natural external view, when the air bag is in a state of non-expanded.

[0044] The invention being thus described, it will be obvious that the same may be varied in many ways. Such variations are not to be regarded as a departure from the spirit and scope of the invention, and all such modifications as would be obvious to one skilled in the art are intended to be included within the scope of the following claims.
